

# Design for Testability

- **Testability Measurement**
- **DFT Basics**
- **DFT Techniques**
  - **ad hoc**
  - **Scan design**
  - **Boundary scan**

# Testability

- **Controllability:** The ability to set some circuit nodes to a certain states or logic values.
- **Observability:** The ability to observe the state or logic values of internal nodes.

# Usage of Testability Measures

- **Speed up test generation**
- **Improve the design testability**
- **Guide the DFT insertion**

# Testability Measurement

- TMEAS [Stephenson & Grason, 1976]
- SCOAP [Goldstein, 1979]
- TESTSCREEN [Kovijanic 1979]
- CAMELOT [Bennetts *et al.*, 1980]
- VICTOR [Ratiu *et al.*, 1982]

# SCOAP

- Sandia Controllability Observability Analysis Program.
- Using integers to reflect the difficulty of controlling and observing the internal nodes.
- Higher numbers indicate more difficult to control or observe.
- Applicable to both combinational & sequential circuits.

# Measurement in SCOAP

- For a node A:

**$CC^0(A)$  : Combinational 0-controllability**

**$CC^1(A)$  : Combinational 1-controllability**

**$SC^0(A)$  : Sequential 0-controllability**

**$SC^1(A)$  : Sequential 1-controllability**

**$CO(A)$  : Combinational observability**

**$SO(A)$  : Sequential observability**

# Combinational Components in SCOAP

Ex:

$$CC^0(x) = CC^0(A) + CC^0(B) + 1;$$

$$CC^1(x) = \min\{CC^1(A), CC^1(B)\} + 1.$$

$$SC^0(x) = SC^0(A) + SC^0(B);$$

$$SC^1(x) = \min\{SC^1(A), SC^1(B)\}.$$

- CC implies the distance from PI
- SC implies the number of time frames needed to provide a 0 or 1.

# Sequential Components in SCOAP

Ex:

- $CC^0(Q) = \min\{CC^0(R), CC^1(R) + CC^0(D) + CC^0(C) + CC^1(C)\}$
- $CC^1(Q) = CC^1(R) + CC^1(D) + CC^0(C) + CC^1(C)$
- $SC^0(Q) = \min\{SC^0(R), SC^1(R) + SC^0(D) + SC^0(C) + SC^1(C)\} + 1$
- $SC^1(Q) = SC^1(R) + SC^1(D) + SC^0(C) + SC^1(C) + 1$

# Observability in SCOAP

- $CO(P) = CO(N) + CC^1(Q) + CC^1(R) + 1$
- $SO(P) = SO(N) + SC^1(Q) + SC^1(R)$

- $CO(R) = CO(Q) + CC^1(Q) + CC^0(R)$
- $SO(R) = SO(Q) + SC^1(Q) + SC^0(R) + 1$

# Initial States

- **PI:  $CC^0 = CC^1 = SC^0 = SC^1 = 1$**
- **PO:  $CO = SO = 0$**
- **All other numbers are initially set to  $\infty$**

# Importance of Testability Measures

- They can guide the designers to improve the testability of their circuits.
- Test generation algorithms using heuristics usually apply some kind of testability measures to their heuristic operations (e.g., in making search decisions), which greatly speed up the test generation process.

# Design for Testability (DFT)

- **Test Costs:**
  - Test Generation
  - Fault Simulation
  - Fault Location
  - Test Equipment
  - Test Application Time
- **Test Difficulties:**
  - Sequential > Combinational
  - Control Logic > Data Path
  - Random Logic > Structured Logic
  - Asynchronous > Synchronous
- **Testability**
  - Controllability
  - Observability

# Design for Testability (DFT)

- **DFT techniques are design efforts specifically employed to ensure that a device is testable.**
- **In general, DFT is achieved by employing extra H/W.**
  - ⇒ **Conflict between design engineers and test engineers.**
  - ⇒ **Balanced between amount of DFT and gain achieved.**
- **Examples:**
  - **DFT**
    - ⇒ **Area ↑ & Logic complexity ↑**
    - ⇒ **Yield ↓**
    - ⇒ **For fixed fault coverage, defect level ↑**
  - **Therefore, DFT must guarantee to increase fault coverage.**

# Benefits of DFT

- In general, DFT has the following benefits:
    - Fault coverage ↑
    - Test generation (development) time ↓
    - Test length
    - Test Memory } hope ↓
    - Test application time
    - Support a test hierarchy {
      - Chips
      - Boards
      - Subsystems
      - Systems
    - Concurrent engineering
    - Reduce life-cycle costs
- ⇒ Pay less now and pay more later without DFT!

# Costs Associated with DFTs

- **Pin Overhead**
- **Area / Yield**
- **Performance degradation**
- **Design Time**

⇒ **There is no free lunch !**

# DFT Techniques

- **ad hoc DFT technology**
- **Scan-based design**
- **Boundary Scan**

# Ad hoc Techniques

- **Test points**
- **Initialization**
- **Monostable multivibrators (one shot)**
- **Oscillators and clocks**
- **Counter / Shift registers**
- **Partitioning large circuits**
- **Logic redundancy**
- **Break global feedback paths**
- **⋮**

# Example of *ad hoc* Techniques

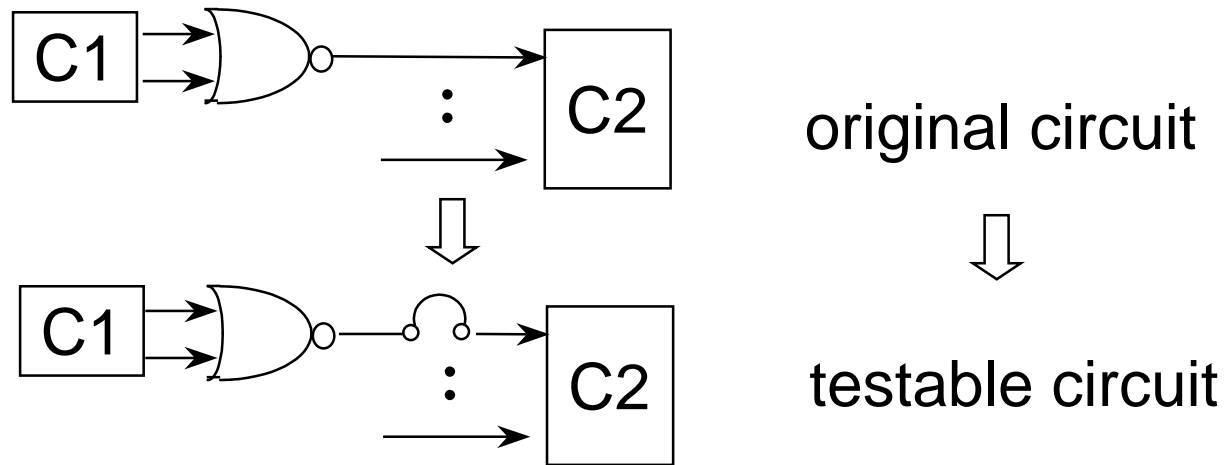

- Insert test point

# Test Points

- Rule : to enhance controllability and observability by inserting control points (cp) and observation points (op), respectively.

• Ex:

⇒ can be done only for board

# Test Points (Cont.)

- Using a CP for 0-injection and an OP for observability:

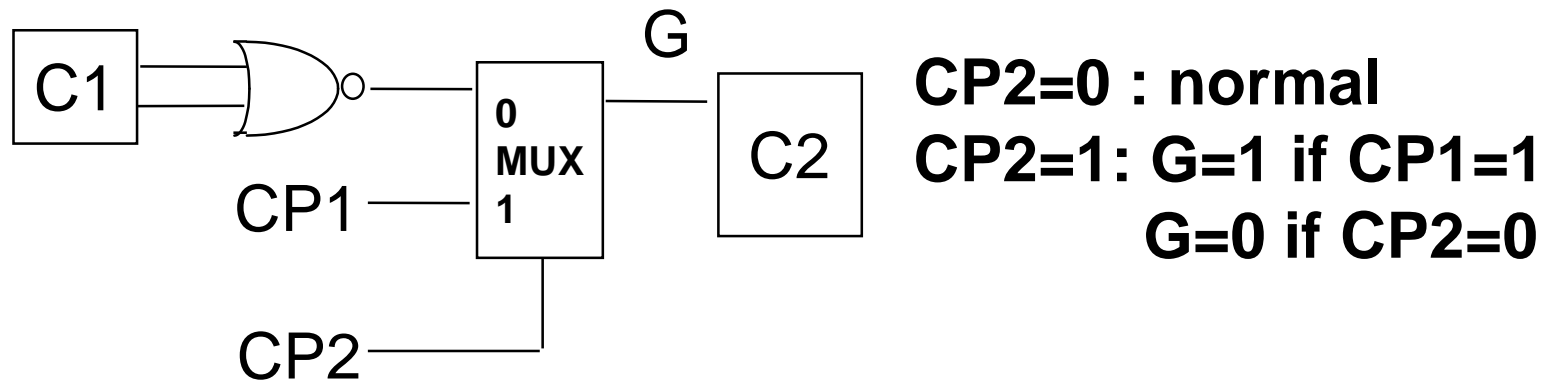

- 0/1 Injection:

# Test Points (Cont.)

- Using a MUX

# Test Points (Cont.)

- **Multiplexing Observation Points:**

- **Demultiplexing and Latching Control Points:**

# Selection of CP

- **Control, address and data bus lines on bus-structured designs.**
- **Enable/hold inputs to microprocessors.**
- **Enable and Read/write inputs to memory.**
- **Clock and preset/reset inputs to F/Fs, counters, shift registers, etc.**
- **Data select inputs to multiplexers and demultiplexers.**
- **Control lines on tri-state devices.**

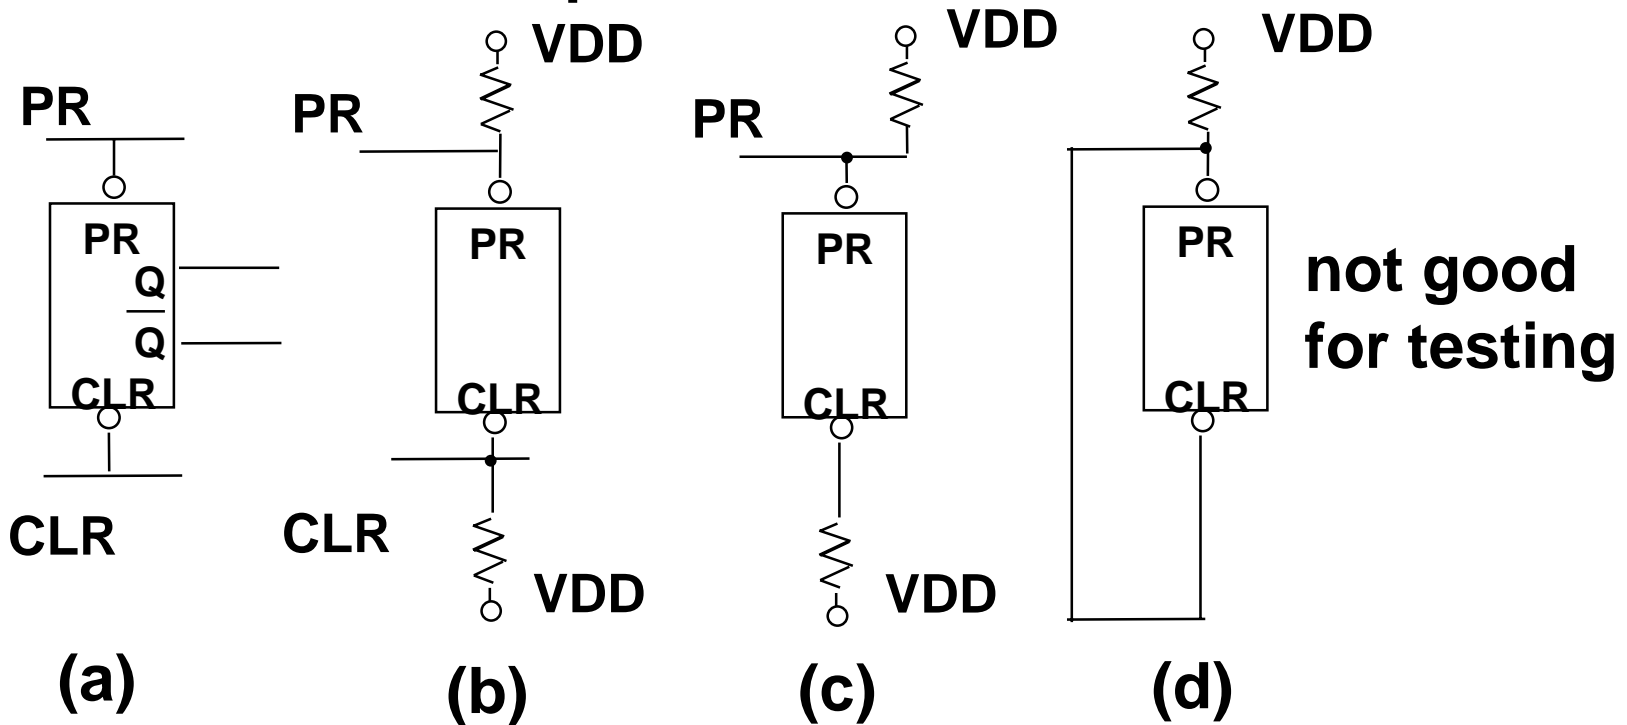

# Selection of OP

- **Stem lines with high fanout.**
- **Global feedback path**
- **Redundant signal lines**
- **Outputs of devices with many inputs, e.g., multiplexers and parity generators.**
- **Outputs from state devices.**
- **Address, control, data buses**

# Initialization

- Rule: Design circuits to be easily initialized
  - Don't disable preset and clear lines

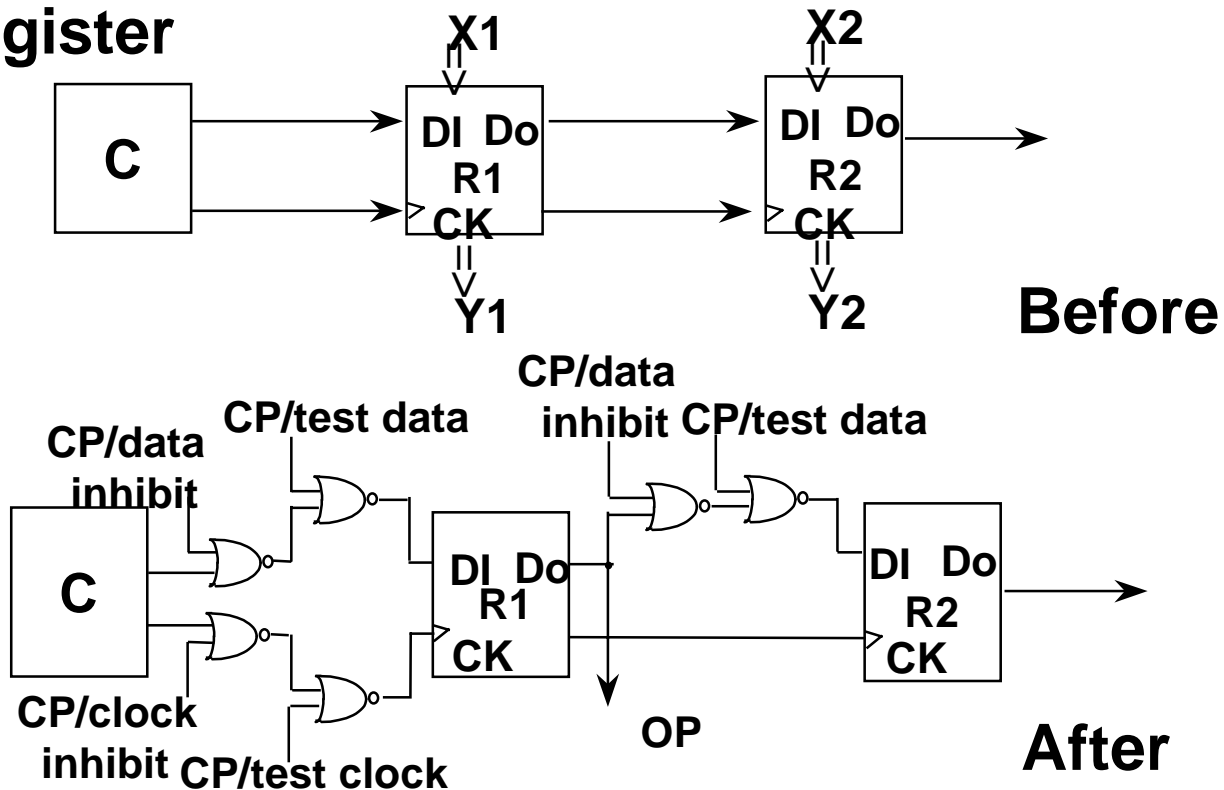

# Monostable Multivibrator, Oscillators and Clocks

- Rule: Disable internal one shot, OSC and clocks
  - inserting CP and/or OP while disabling these devices
- Example:

# Partitioning Counters and Shift Registers

- Rule: Partition into small units
- Ex: Register

# Partition of Large Combinational Circuits

- Rule : To reduce test generation costs and/or test application time

$T_1$	$T_2$	Mode
0	0	normal
0	1	test $C_1$
1	0	test $C_2$

If  $2^{p+n} + 2^{q+m} < 2^{m+n}$  then test time can be reduced

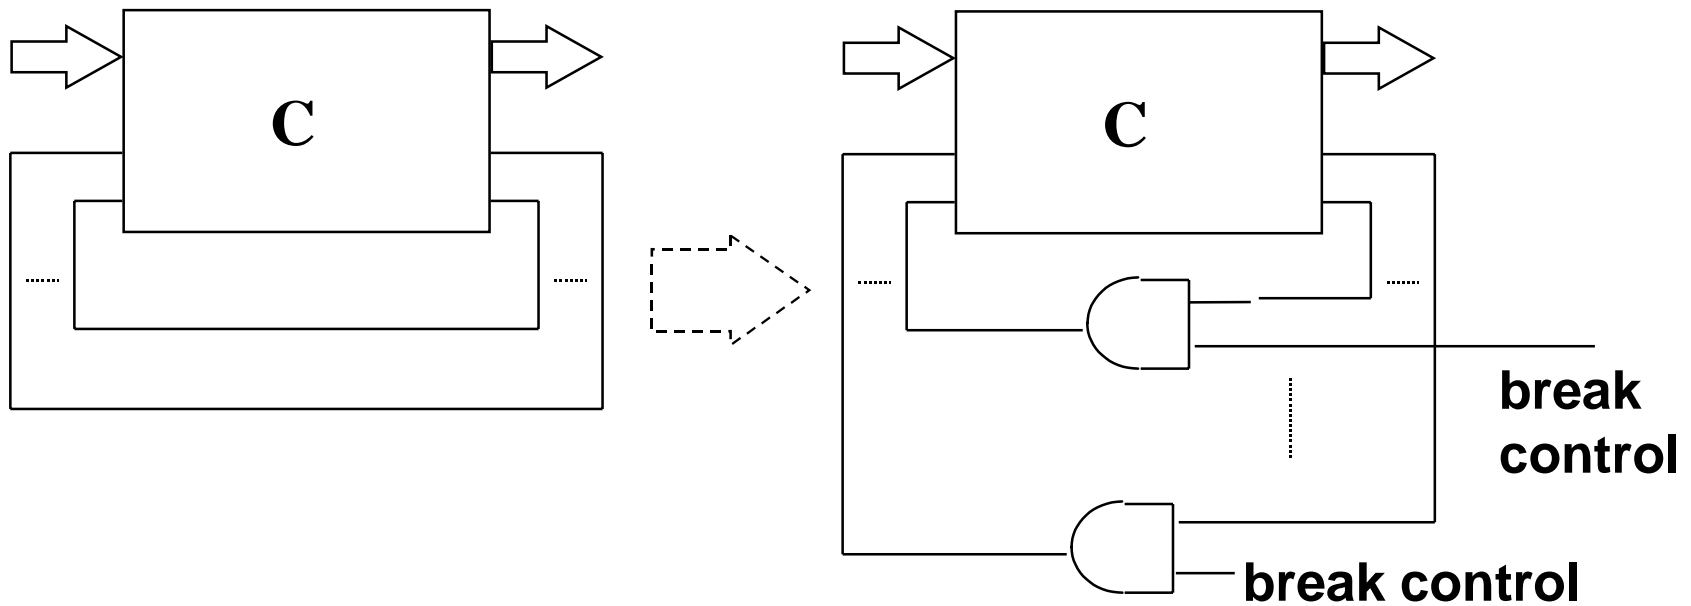

# Logic Redundancy

**Rule: Avoid or eliminate redundancy ckt.**

- **Design errors**
- **Undetectable faults**
- **Invalidation of some tests**
- **Bias fault coverage**

# Global Feedback Paths

**Rule: break global feedback**

# Scan System

**Original design**

**Modified circuit**

# Full Serial Integrated Scan

**CK**  
Normal

**CK**  
Scanned

**Sequential ATPG → Combinational ATPG**

# Isolated Serial Scan (Scan/set)

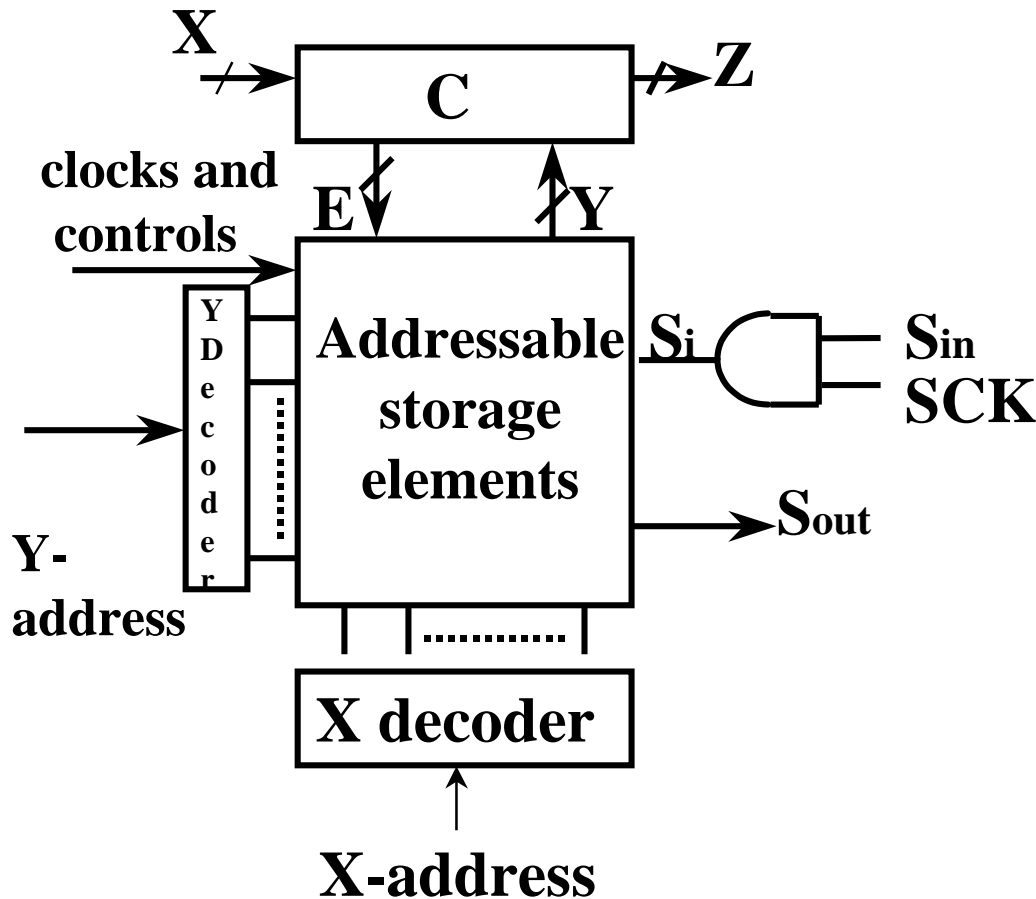

# Full Isolated Scan (Structured)

- Shadow register
- Real-time test support
- snapshot

# Random-Access Scan (Non serial-structured)

- High area overhead
- Faster test application: only bit change
- Concept of crosscheck

# Scan Cell Design

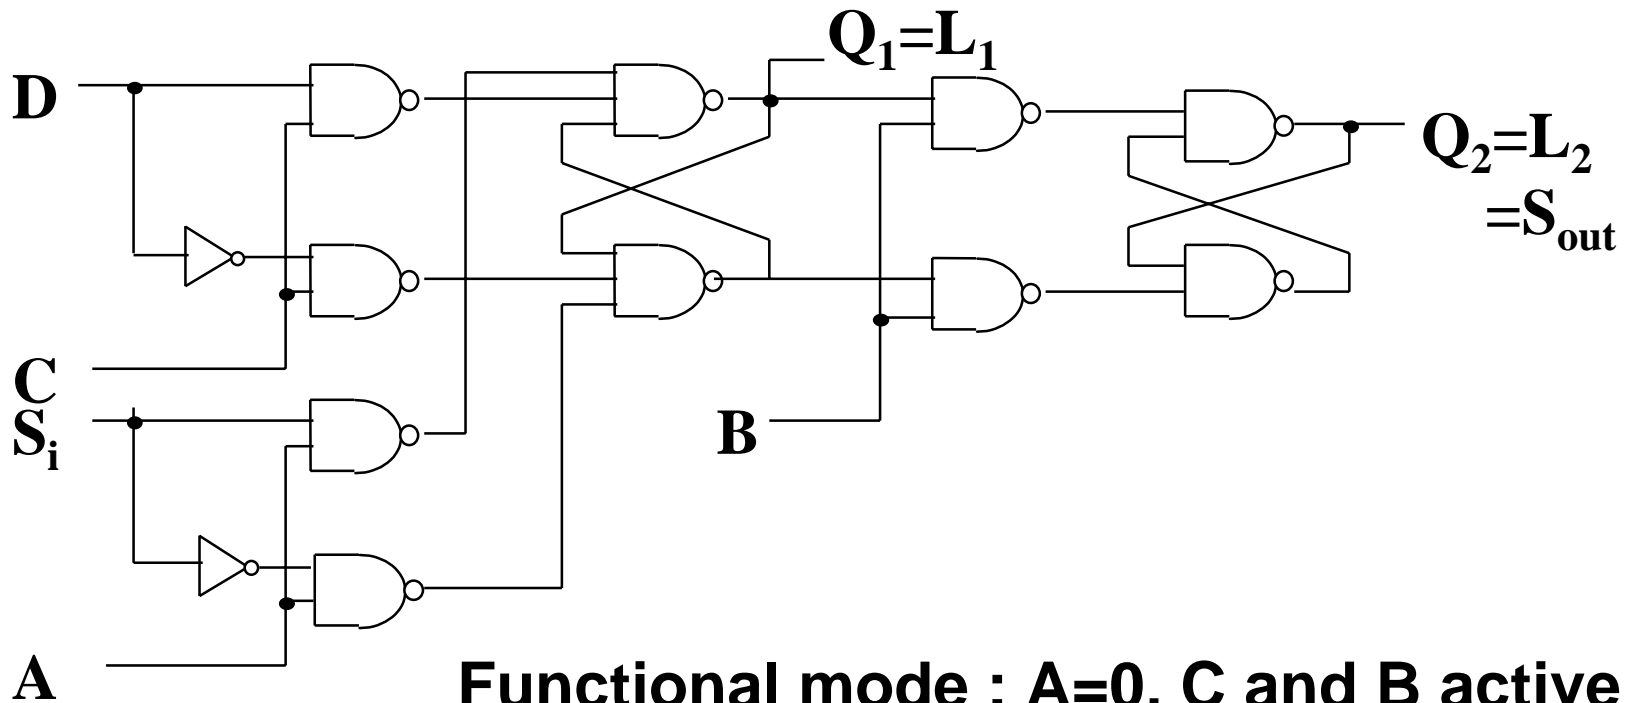

- **Static / Dynamic**
- **Single / Double stages**
- **Latch / Flip-flop (Clocking Scheme)**

## **Usually Two Operation Modes**

- **Functional mode**
- **Shift mode**

# IBM LSSD Scan Cell

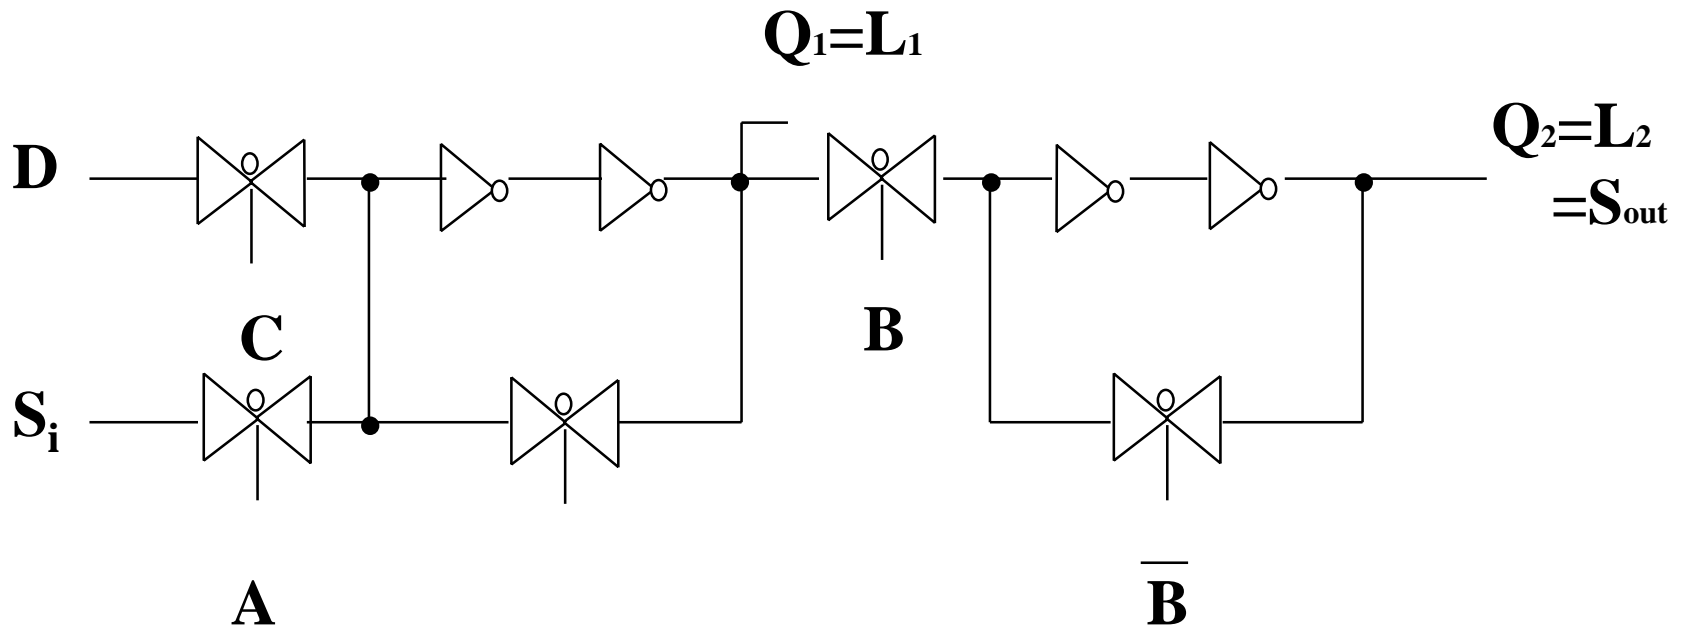

- Gate Level

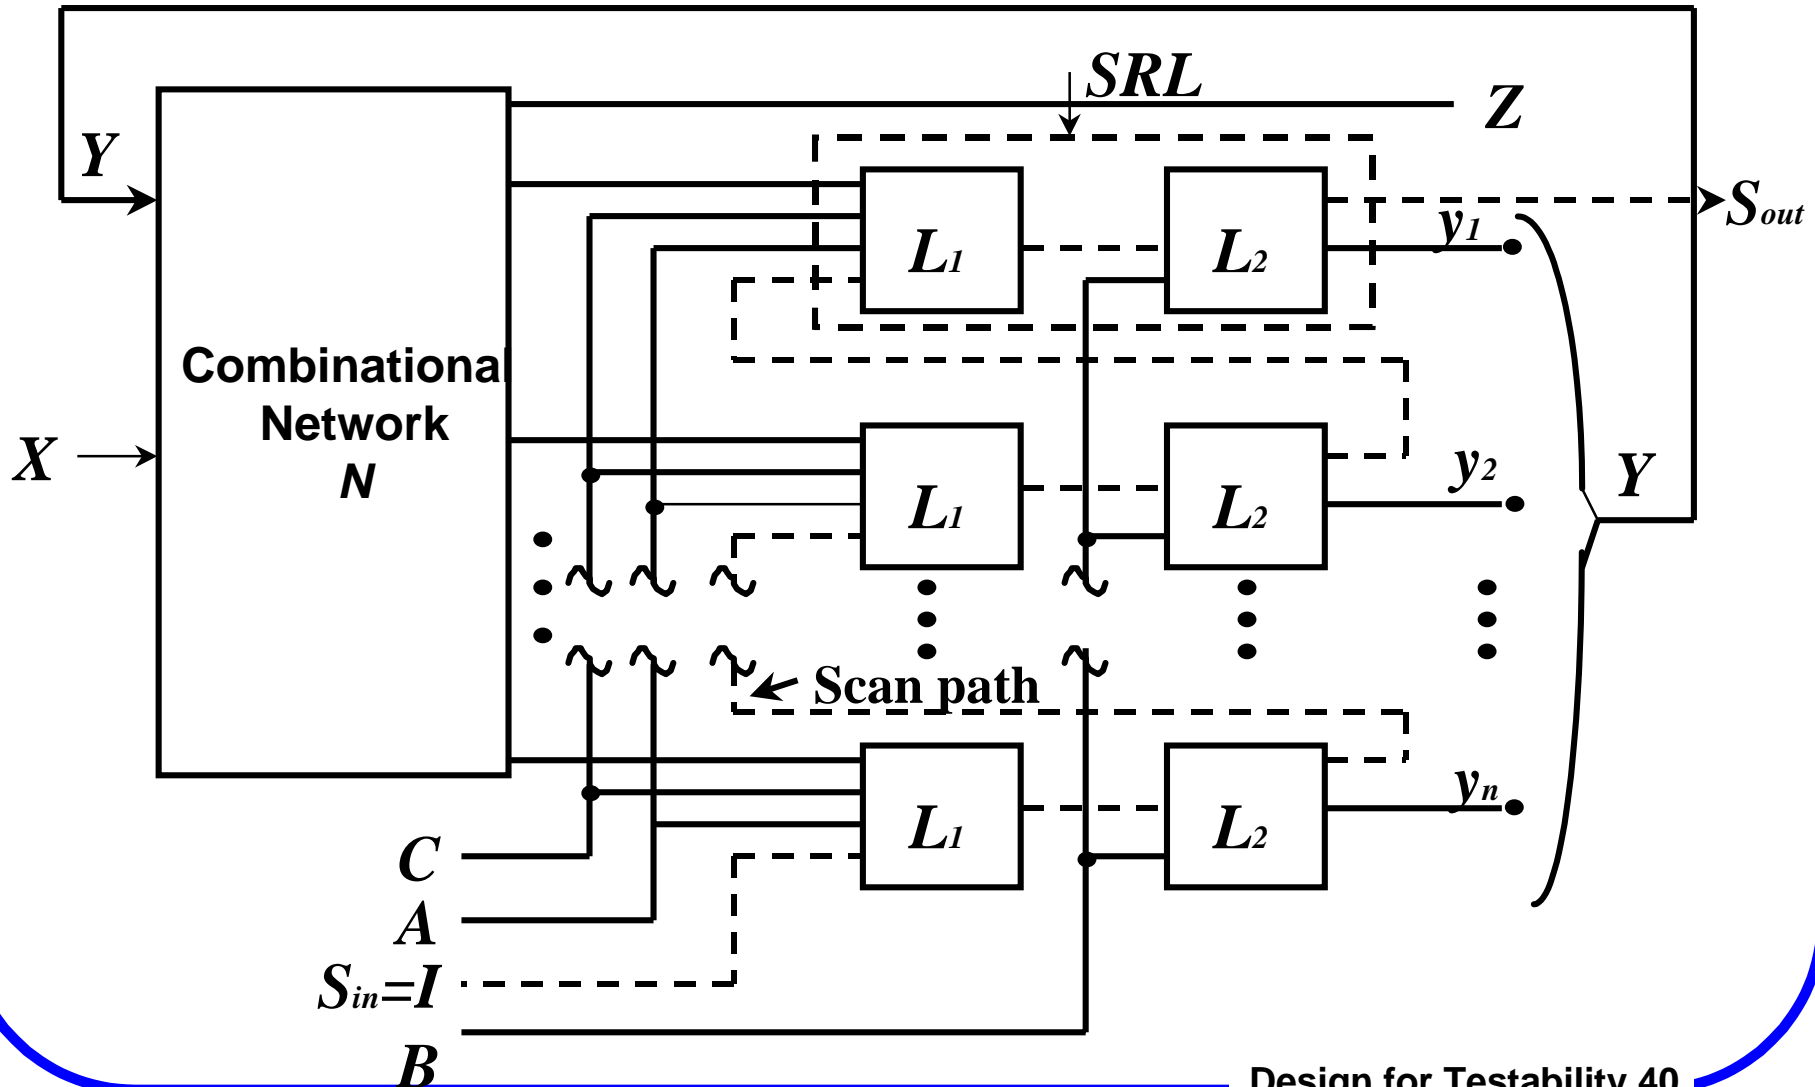

Functional mode :  $A=0$ , C and B active  
Test(Shift) mode :  $C=0$ , A and B active

# IBM LSSD Scan Cell (Cont.)

- Switch / Inverter level

# LSSD Double-Latch Design

# Clocking Scheme of LSSD Double-Latch

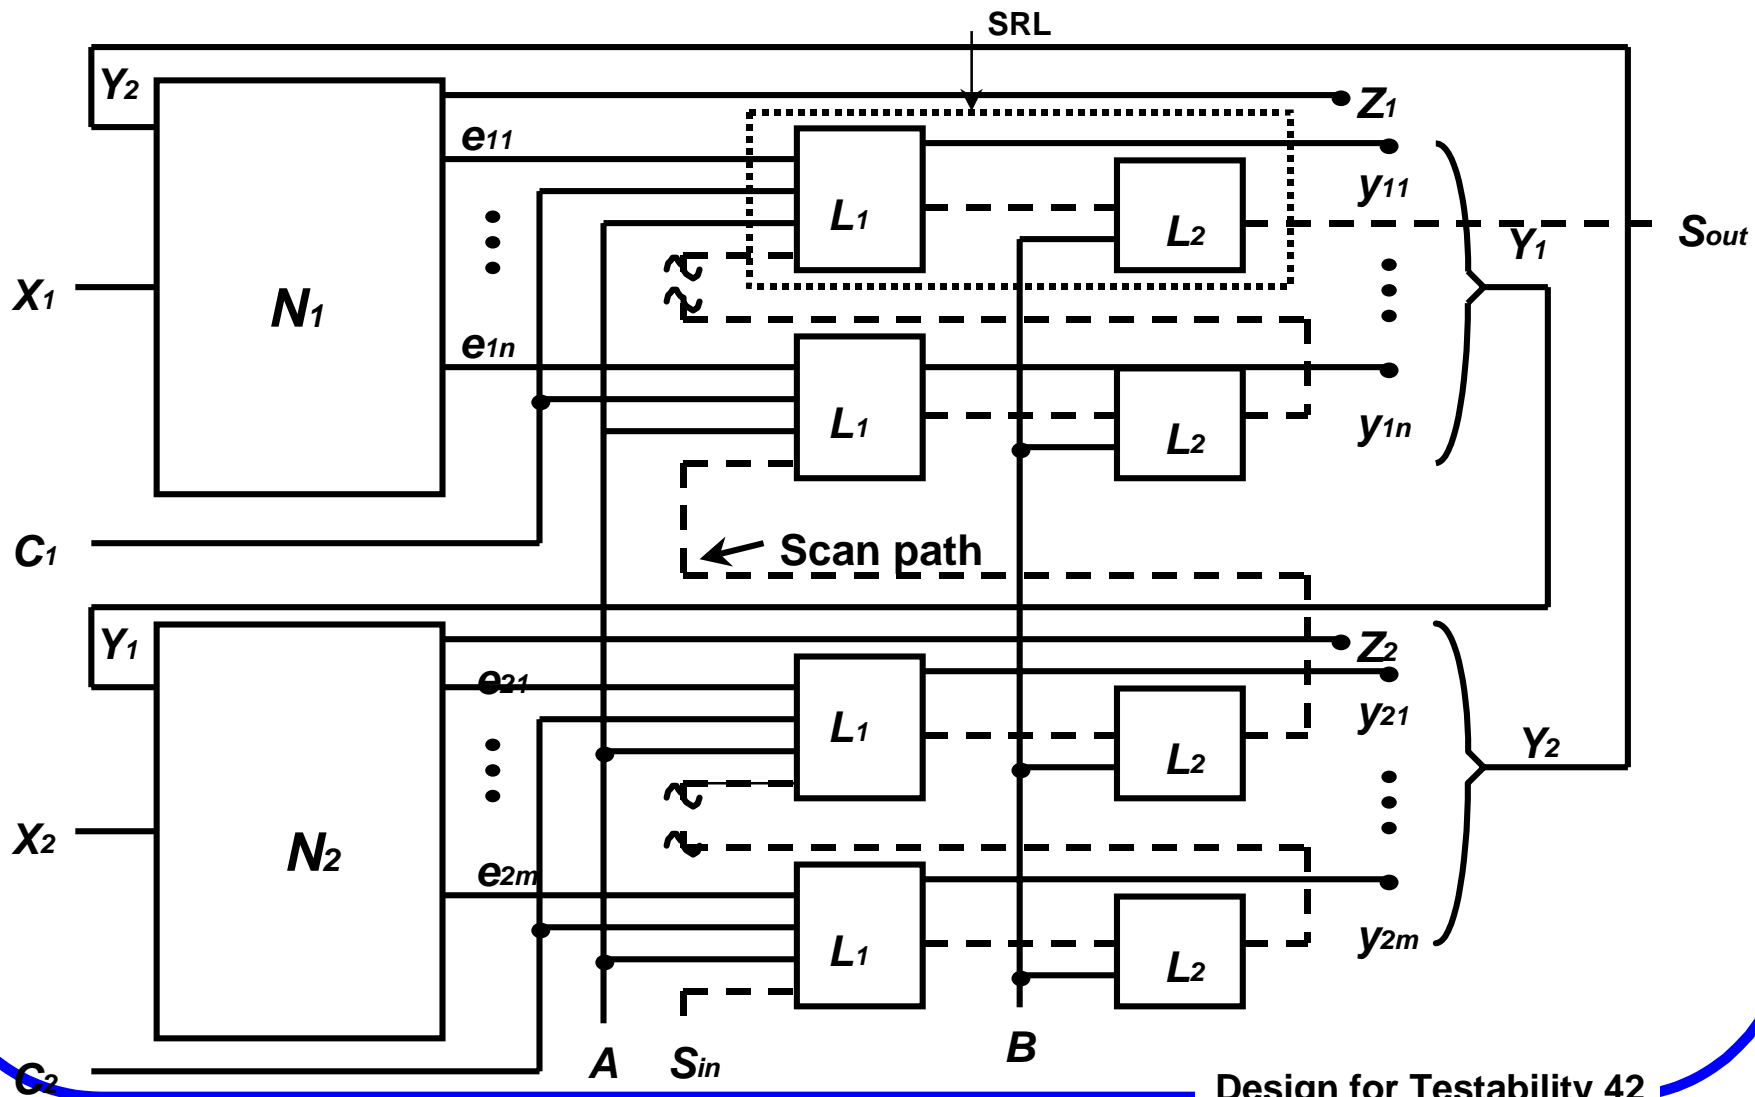

**Normal mode:**

**Test mode:**

# LSSD Single-Latch Design

# Scan Design Costs

- **Area overhead**
- **Possible performance degradation**
- **Extra pins**
- **High test time**
- **Extra clock control**

# Advanced Scan Concepts

- Partial scan (P.S.)
- Multiple test session (M.T.S.)
- Multiple scan chains (M.S.C.)
- Broadcast scan chains (B.S.C)

Method	P.S.	M.T.S.	M.S.C.	B.S.C.
Area overhead	↓	same	same or ↑	same
Performance Degradation	↓	same	same	same
Extra pins	same	same	same or ↑	↓
Extra clock control	same	same	same	same
Test application time	↓ or ↑	↓	↓	↓

# Partial Scan: Only a subset of all flip-flops are scanned

- **Trade-off between**

- Area overhead
- Test generation complexity

# **Partial Scan by Cheng & Agrawal**

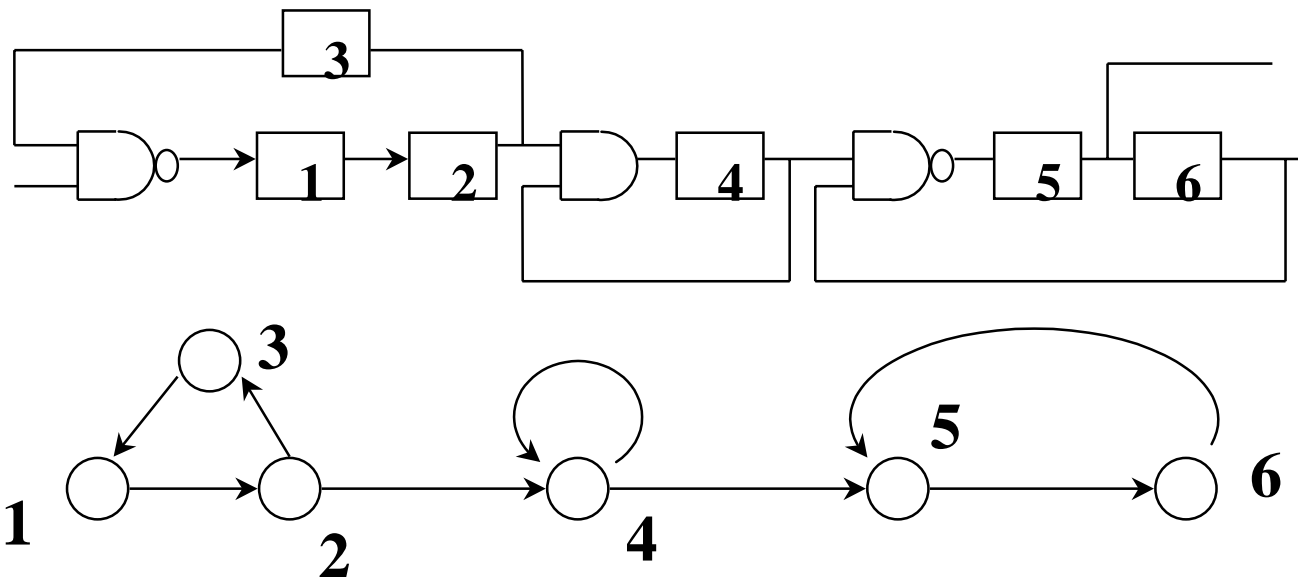

**(pp. 544-548, IEEE Trans. Computers, Apr. '90)**

- **Basic idea:**
  - **Representing a circuit as a directed graph**  
 **$G=(v,E)$**
  - **Trying to break cycles and reducing sequential depth**

# Graph Representation

- Each flip-flop  $i \Rightarrow$  a vertex  $V_i$
- Each combinational path from  $FF_i$  to  $FF_j \Rightarrow$  an edge from  $V_i$  to  $V_j$

**Ex:**

# Graph Representation

**Def: Distance between two vertices on a path = # of vertices on that path**

# Graph Representation

**Def: sequential depth of a circuit = the distance of the longest path**

**Def: Cycle length = maximum # of vertices in a cycle**

**EX: dist = 6**

# Analysis of Sequential Circuits

- Any sequential circuit can be divided into 3 classes of subcircuits based on the directed graph representation
  1. acyclic directed
  2. directed with only self loops
  3. directed with cycles of two or more vertices

Ex:

1.

# Analysis of Sequential Circuits (Cont.)

2.

3.

# Experimental Results

- **Experimental results show that**
  - **# of gates or # FF's is not the dominant factor for test generation complexity**
  - **Cycle length is the dominant factor**
  - **Sequential depth is minor**
- ⇒ **To reduce test generation complexity, cycles of length  $\geq 2$  should be eliminated**

# Flip-Flop Selection Algorithm

- **Identify all cycles**
  - **Repeat**
    - for each vertex**
      - count the frequency of appearance in the cycle list
      - select the most frequently used vertex**
      - remove all cycles containing the remove (selected) vertex
    - until (cycle list is empty)**
- ⇒ **This is a feedback vertex set problem, a well-known NP-complete problem, hence heuristic is used.**

# Experimental Results (Cheng & Agrawal '90)

## PARTICAL SCAN FOR MULT4 (382 GATES, 15 FLIP-FLOPS)

No. Of scan FFs	Max cycle length	Depth	CPU sec.		Fault cov.	No. Of test	Total vector
			Test gen.	Fault sim.			
0	4	13	75	5	98.01%	115	115
5	1	6	8	2	99.68%	69	345
6	1	4	8	2	99.68%	72	432

## PARTICAL SCAN FOR CHIP-A (1112 GATES, 39 FLIP-FLOPS)

No. Of scan FFs	Max cycle length	Depth	CPU sec.		Fault cov.	No. Of test	Total vector
			Test gen.	Fault sim.			
0	1	14	269	274	98.80%	868	868
8	1	10	85	56	99.60%	529	4132
16	1	6	49	33	99.80%	387	6192

# The BALLAST Methodology

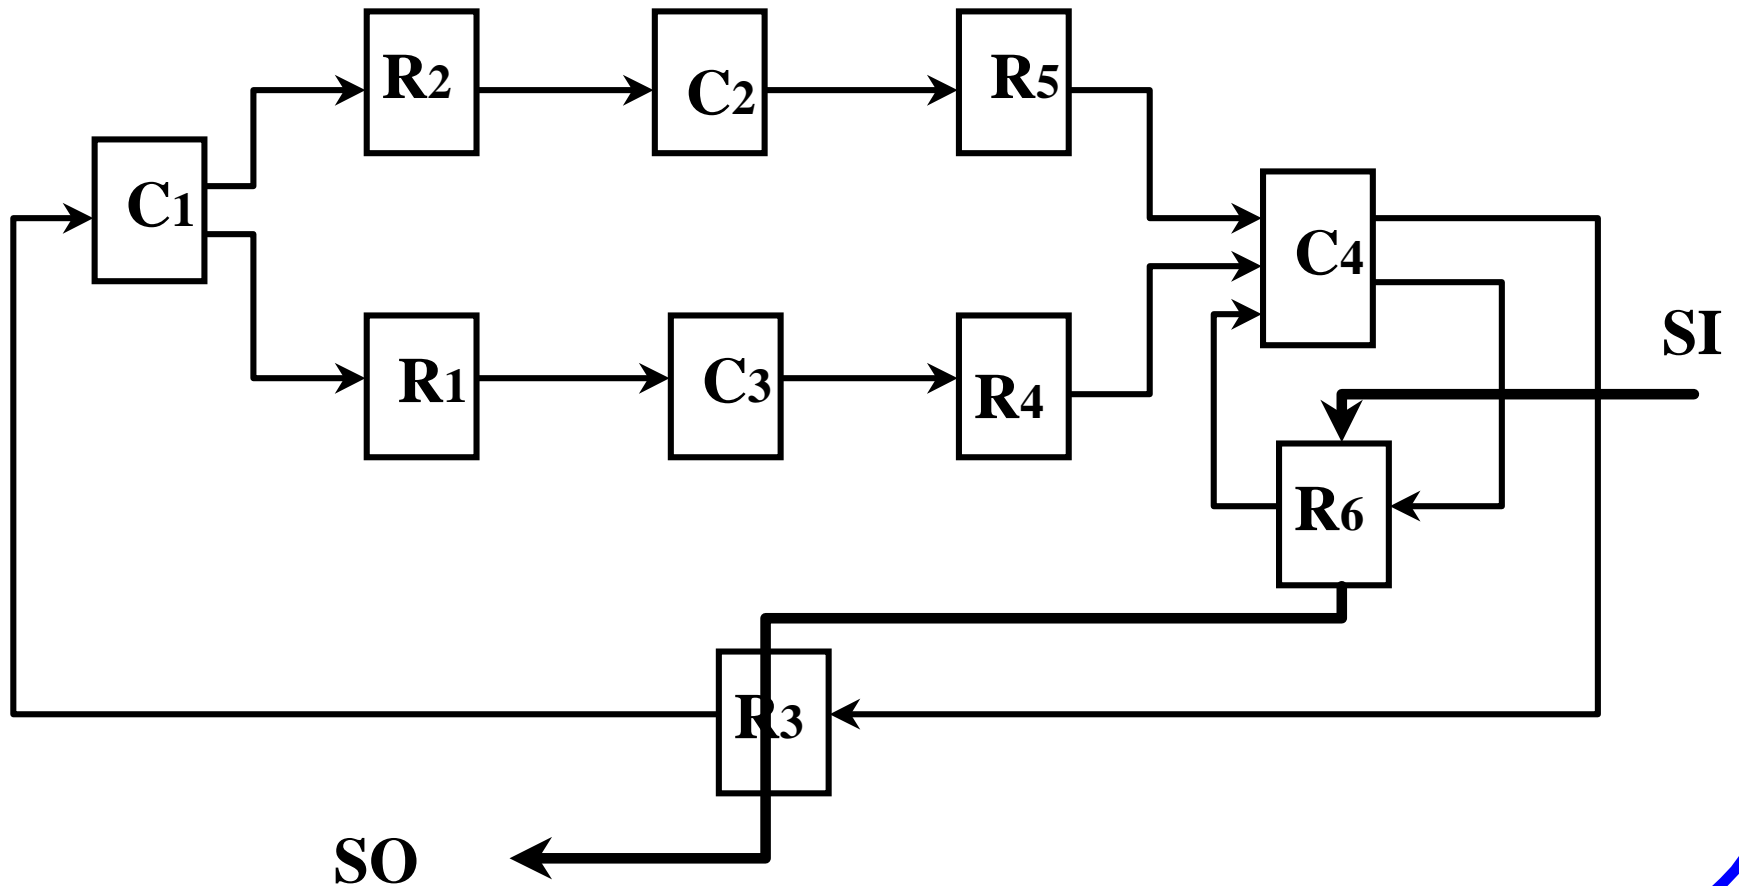

(Rajesh Gupta, Rajiv Gupta, M.A.Breuer,  
IEEE T-Computers, Apr.'90)

- Scan storage elements are selected such that remainder of the circuit has some desirable structure.
- A complete test set can be obtained using combinational ATPG.

# Example

Fig.1

## Example (Cont.)

- **Test procedure:**
  - **Scan in a test pattern to R3 and R6 .**
  - **Hold test pattern in R3, R6 for two clock cycles such that test response appears in R5 and R4.**
  - **Load data (from R5, R4) to R6, R3 and shift out**

# Circuit Model

- **Register:**
  - Collection of one or more FF's driven by the same clock signal and (if any) mode control signal.
- **Two types of registers:**
  - Load set L - the set of registers whose FF's have no explicit load enable control => always operate in LOAD mode.
  - Hold set H - two modes of operations : LOAD and HOLD.
- In the previous example, R1, R2, R4, R5 belong to LOAD set, and R3, R6 belong to Hold set H.

# Circuit Model (Cont.)

- **Clouds**

- The combinational logic in a circuit  $S$  can be partitioned into clouds, where each cloud is a maximum region of connected combinational logic such that its inputs are either PIS or outputs of FF's and its outputs are either POS or inputs to FF'S.

- **Ex**

- In Fig.1 each block of C1, C2 , C3 and C4 represents a cloud.
- ⇒ No two clouds can be directly connected together.
- ⇒ Each FF ( in any register ) must receive data from exactly one cloud and must feed exactly one cloud.
- ⇒ FF's can be grouped into registers such that each register receivers data from exactly one cloud and feeds exactly one cloud.

# Topology graph $G=(V, A, H, W)$

**V: set of clouds.**

**A: connections between clouds through registers.**

**H: arcs in  $H \subset A$  represents HOLD registers.**

**$w:A \rightarrow Z_+$  ( positive integers) defines the number of FF'S in each register.**

**$\Rightarrow w(a)$  represents the cost of converting register  $a$  into a scan path register.**

# Example

# B-structure

- **S**: a synchronous sequential circuit with topology graph  $G=(V, A, H, W)$ .
- **S** is said to be to a balanced sequential structure (B-structure) if
  - **G** is acyclic.
  - $\forall v_1, v_2 \subset V$ , all directed paths from  $v_1$  to  $v_2$  are of equal length.
  - $\forall h \subset H$ , if  $h$  is removed from **G**, the resulting graph is disconnected.
- When considering whether a circuit with scan registers is a B-structure, the arcs corresponding to scan registers must be removed.
- Condition 3 means that the removed of in the scan path will disconnect the graph.

# Kernel :The circuit excluding the scan path

- **Combinational equivalent of  $C^B$  of a B-structure  $S^B$  : the combinational circuit formed by replacing each FF in every register in  $S^B$  by a wire.**
- **Depth d of  $S^B$  :the longest directed path in the topology graph**

# Examples:

Kernel of Fig.1

Combinational  
equivalent

- **Given an input pattern  $I$  applied to  $S^B$ , the single - pattern output of  $S^B$  for  $I$  is defined as the steady - state output of  $S^B$  when  $I$  is held constant and all registers are operated in LOAD mode for at least  $d$  clock cycles**
- **Given some fault  $f$  in  $S^B$ , if the single-pattern outputs for  $I$  of the good and faulty circuits are different , then  $I$  is a single -pattern test for  $f$** 
  - ⇒ **B - structures : (1) single -pattern testable (2) complete single - pattern test set can be derived using combinational test generation techniques**

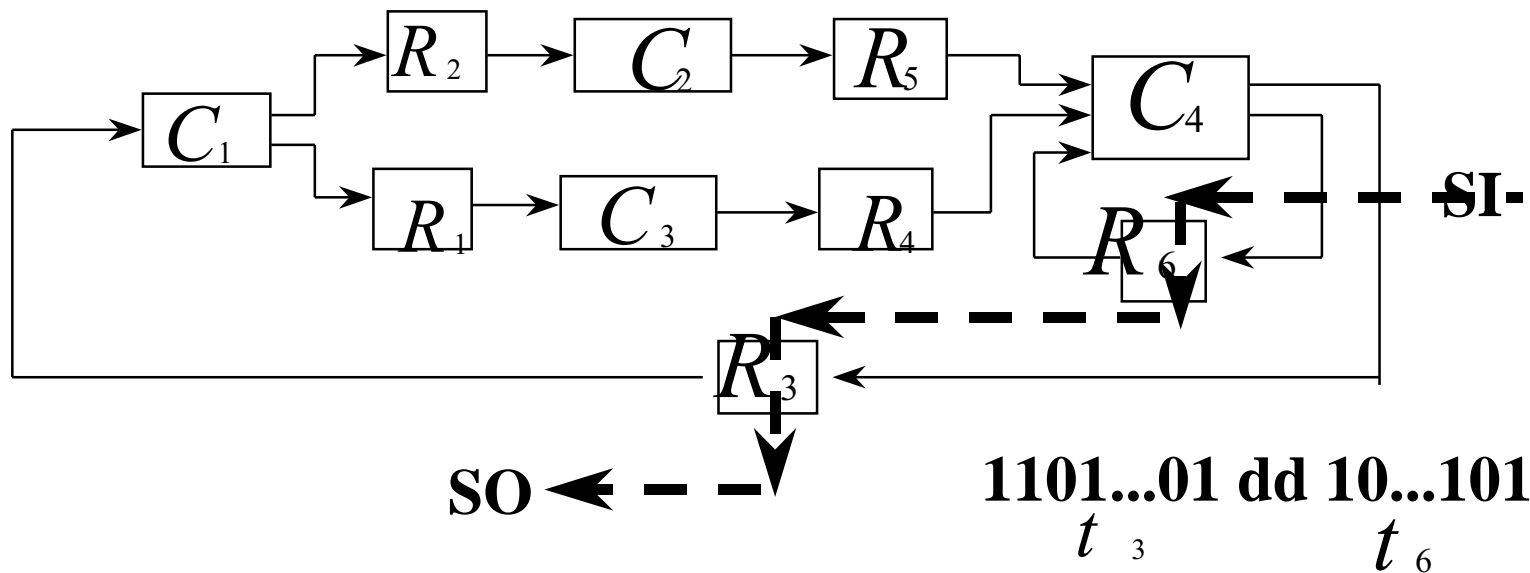

# Outline of BALLAST

- (1) Construct the topology graph  $G$  of the circuit**
- (2) Select a minimal cost set of arcs  $R$  to be removed from  $G$  such that the remaining topology graph is balanced. let  $S^B$  be the  $B$  - structure corresponding to the resulting topology graph**
- (3) Determine  $C^B$  of  $S^B$ . Using a combination ATPG to determine a complete test set  $T$  for  $C^B$**
- (4) Construct a scan path by appropriately ordering the registers in  $R$  and connecting them so that they can both “shift” and “hold”**  
**⇒ Later some “hold” can be released**

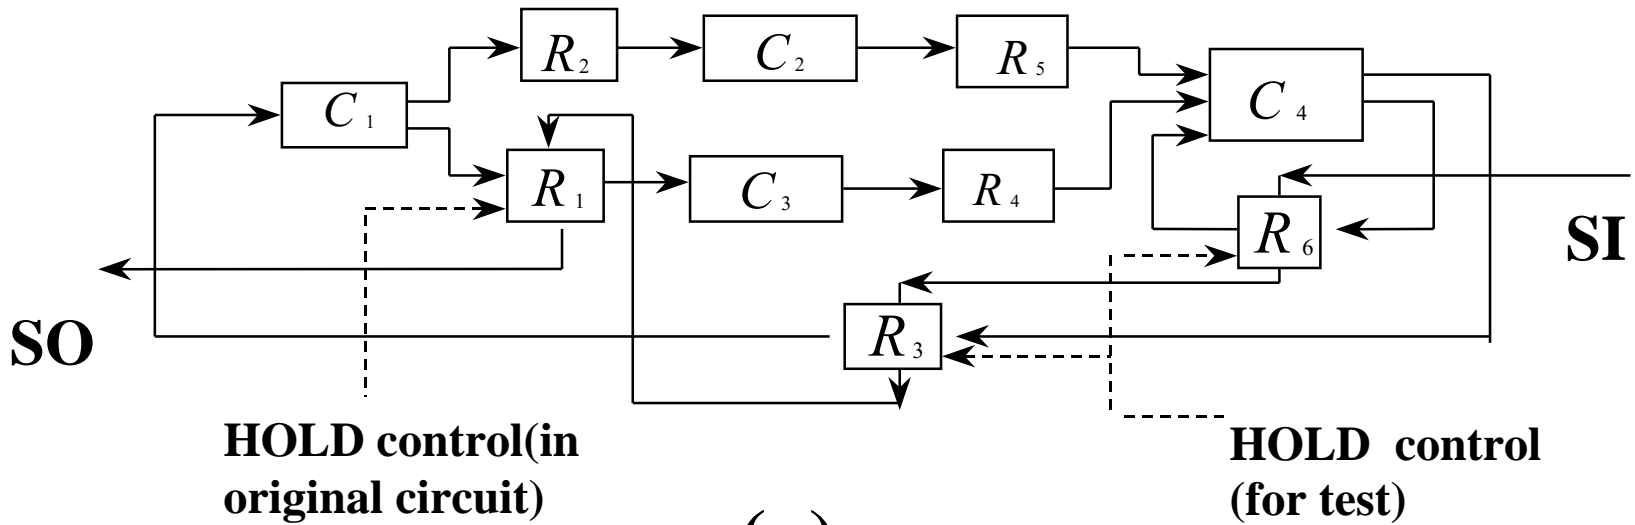

# Selection of Scan Registers

- (1) Transform  $G=(V,A,H,W)$  into an acyclic topology graph  $G_A$  by removing a set of “feedback” arcs  $R_A$  such that  $\sum_{a \in R_A} w(a)$  is minimized
- (2) Transform  $G_A$  into a balanced topology graph  $G_B$  by removing a set of arcs  $R_B$  such that  $\sum_{a \in R_B} w(a)$  is minimized  $R = R_A \cup R_B$  is the desired set of registers
- Both (1) , (2) are NP-complete. Refer to the paper for a heuristic for (2)

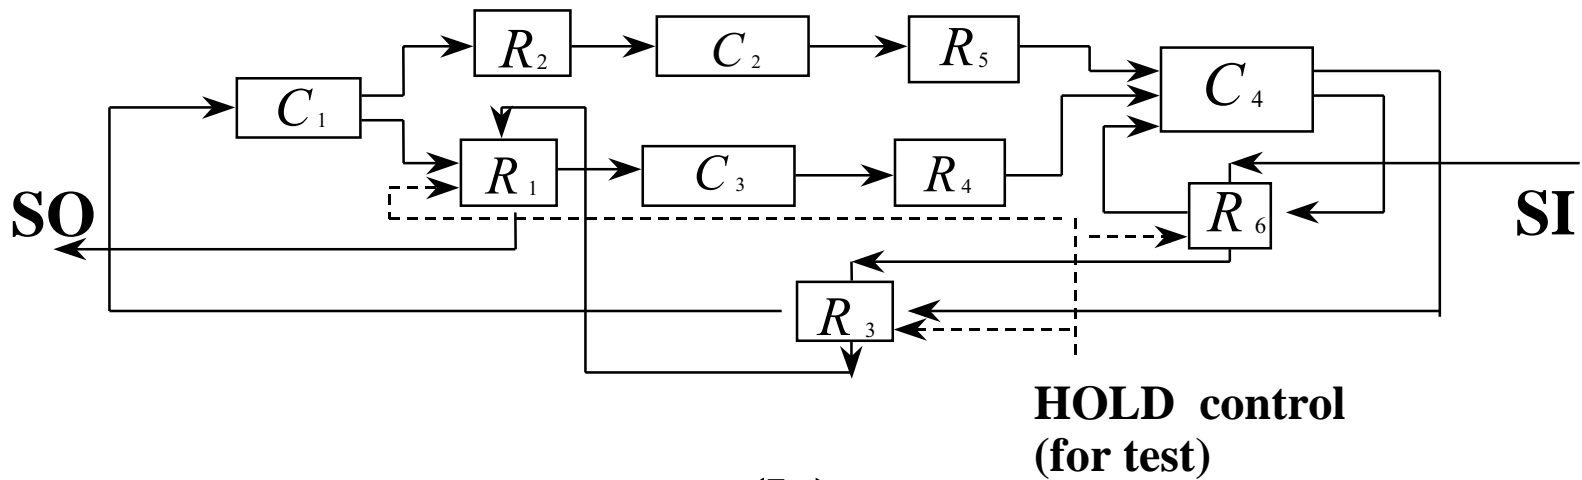

# Eliminate on HOLD mode of Scan Registers

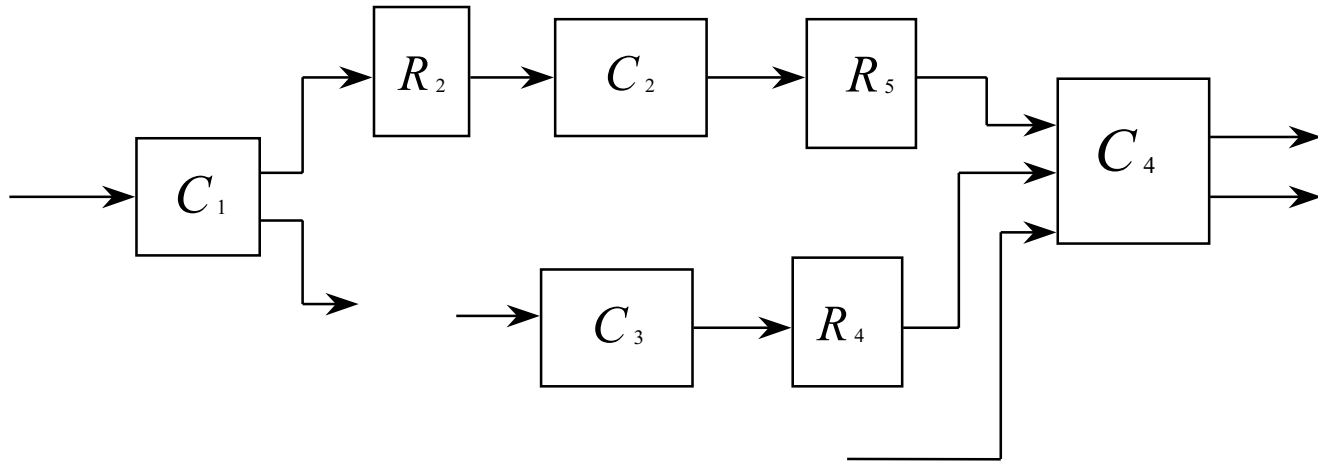

- By adding two dummy bits between the patterns to be scanned to  $R_3$  and  $R_6$ , the HOLD mode can be eliminated

**(a)**

**(b)**

(c)

(d)

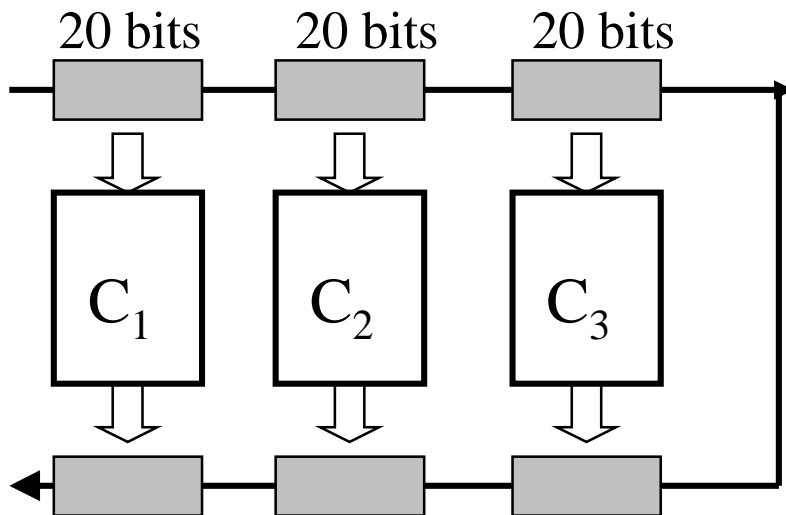

# Test Procedure

- (1) all scan registers in SHIFT mode for 1 clock cycle**
- (2) Repeat N times**
  - a. HOLD all scan registers , LOAD all other for d cycles**
  - b. LOAD all scan registers for 1 clock cycle**
  - c. SHIFT out scan data**

# Multiple Test Session

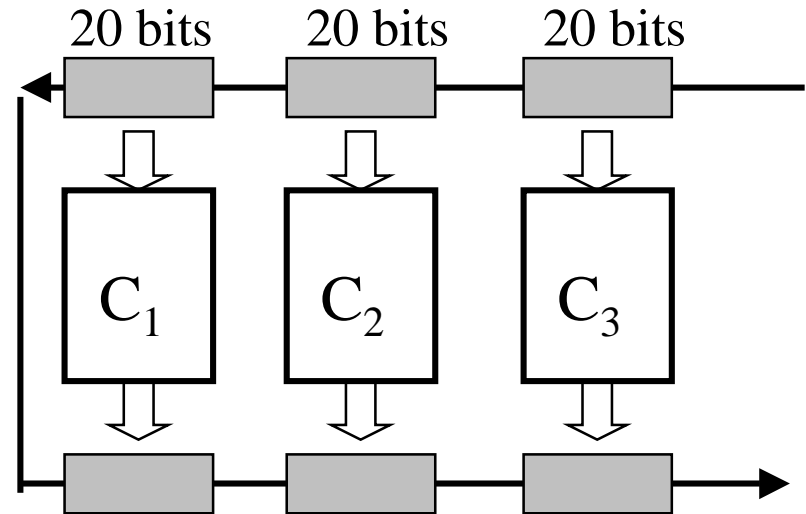

- # patterns:  $C_1$  :100,  $C_2$ : 200 and  $C_3$ : 300

**Test Time**

$$= 60 * 300$$

$$= 18,000 \text{ (cycles)}$$

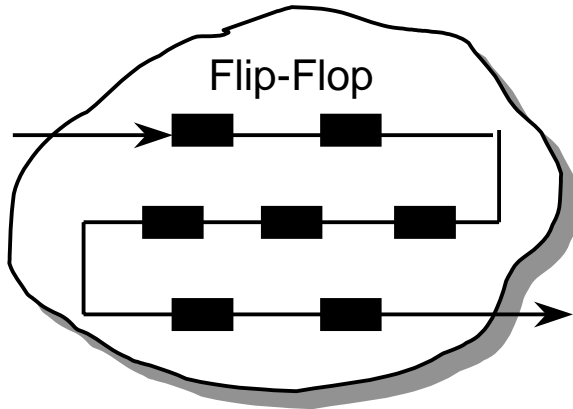

**Test Time**

$$= 60 * 100 + 40 * 100 + 20 * 100$$

$$= 12,000 \text{ (cycles)}$$

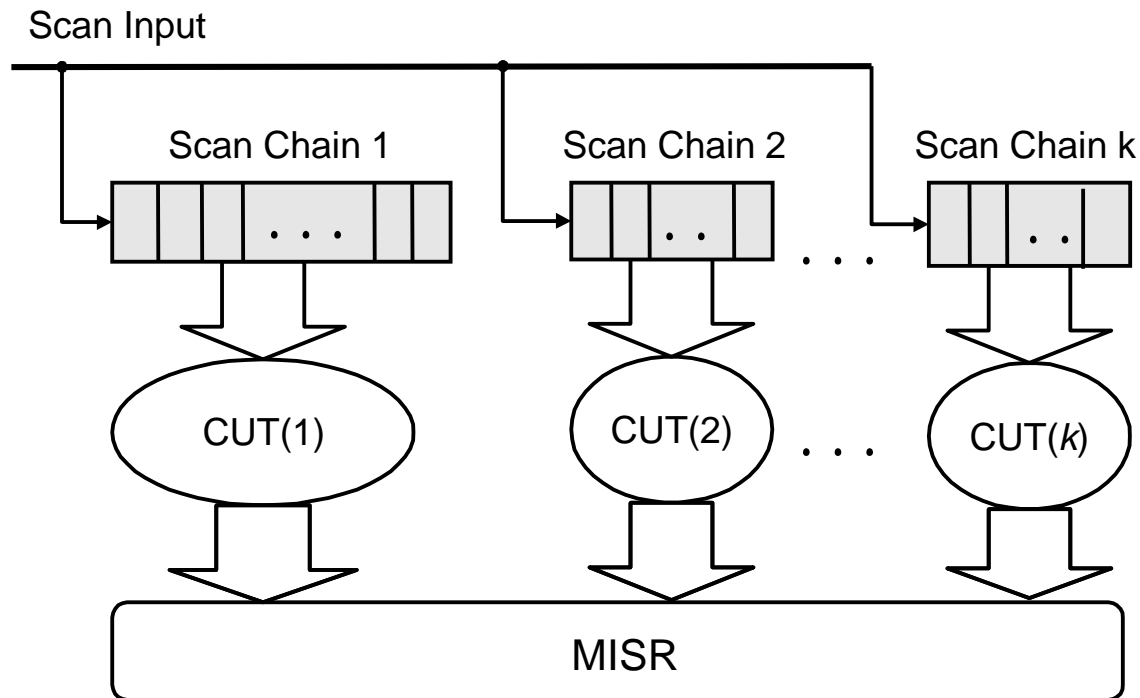

# Multiple Scan Chains

- Reduce test application time
- Usually test I/O will share the normal I/O

# Broadcast Scan Chains- General Hardware Architecture

- Using a single data input to support multiple scan chains

# Virtual Circuits

- The inputs of CUTs are connected in a 1-to-1 manner.

*Example :*

(a) i-to-i connection

(b) random connection

- ➔ The whole virtual circuit is considered as one circuit during ATPG.
- ➔ The resulting test patterns can be shared by all CUTs.

# Experimental Results
